# About MapReduce

- Software framework developed for processing large cluster of data
- Parallel computation using large cluster of commodity machines
- MapReduce classify data with key value. Then summarizes data with user defined command
- MapReduce consists of “**Map function**” and “**Reduce function**”
- **Map function** processes input and returns intermediate key/value pair
- **Reduce function** merges all the intermediate pairs and summarize them

# Model Explanation

# How It Actually Operates

## Further Information

### *Fault Tolerance*

#### Worker Failure

- When worker machine fails,
- Failed workers are marked as idle
- New Map machine's saving location will be

#### Master Failure

- Master occasionally leaves checkpoint
- If master dies, another candidate will continue from that checkpoint
- If there is only one master machine, execute operation again

### *Locality*

- There will be 'M' mappers and 'R' reducers
- It's good for 'M' and 'R' to outnumber a # of machines
- Spited input pieces should not be to big
- Effective *"Dynamic load balancing"*

## Further Information

*Task Granularity*

*Backup Task*

# Experiment / Implementation

*Experiment Environment*

*1TB of Input Data*

*Experiment done in two ways; 'Grep' and 'Sorting'*

## Last But Not Least

Thank you
